Primary Amebic Meningoencephalitis (PAM)

*Naegleria fowleri* is the causative agent for Primary Amebic Meningoencephalitis (PAM). It is a freshwater ameba commonly found in the environment worldwide. Most commonly, this ameba is found in warm bodies of fresh water, such as lakes, rivers, and hot springs, warm water discharge from industrial plants, under-chlorinated swimming pools, and soil. *Naegleria fowleri* is the only species of *Naegleria* that has been found to infect humans. Although *Naegleria fowleri* is commonly found in the environment, infection occurs rarely. However, this disease has public health importance because of its high fatality rate. Only 1 person out of 123 known infected individuals in the United States from 1962 to 2011 has survived. *Naegleria fowleri* infection cannot be spread from person to person contact and will not occur as a result of drinking contaminated water.

Infection with *Naegleria fowleri* is most common during the summer months of July, August, and September. They usually occur when it is hot for prolonged periods causing higher water temperatures, lower water levels and people tend to have increased recreational contact with fresh water. Infections have been observed to increase during heat wave years primarily in southern tier states however recent cases in Kansas, Minnesota and Virginia indicate an expanding geographical area where the organism appears to be thriving. In the United States, it has caused infections in 17 states (AR, AZ, CA, FL, GA, KS, LA, MO, MN, MS, NC, NM, NV, OK, SC, TX, and VA).

Prior to 2008, primary amebic meningoencephalitis was not a reportable disease in Florida. However, 33 cases have been documented with Florida exposures from 1962 through 2011. Of the 33 cases, 22 were exposed in Central Florida. Reported cases described exposures in the following counties: Baker, Brevard, Broward, Citrus, Lee, Madison, Orange, Pasco, Pinellas, Polk, Putnam, Palm Beach, Seminole, Volusia and 3 unknown counties. All cases died from the disease. All but three cases were residents of Florida.

Infection with *Naegleria fowleri* typically occurs when the ameba enters the body through the nose. The ameba travels up the nose to the brain and spinal cord where it destroys the brain tissue causing the disease primary amebic meningoencephalitis (PAM). Generally, exposure to the ameba occurs when people use warm freshwater for activities like swimming, diving, or other rigorous activities in freshwater. Two recent cases of PAM in the USA linked to the use of household tap water for irrigation of sinuses. It is unknown why certain persons become infected with the ameba while millions of others exposed to warm recreational fresh waters do not, including those who were swimming with people who became infected.

The initial symptoms of PAM start 1 to 14 days after infection. Initial signs and symptoms of PAM include headache, fever, nausea, vomiting, and stiff neck. As the ameba causes more extensive destruction of brain tissue this leads to confusion, lack of attention to people and surroundings, loss of balance and bodily control, seizures, and hallucinations. The disease progresses rapidly and infection usually results in death within 3 to 7 days. There have been two documented instances of PAM cases surviving in North America, one in California and the other in Mexico. While prompt diagnosis and medical treatment may influence successful treatment it is unclear what specific treatment regimen is effective. Additional treatment information for healthcare professionals can be found at [www.cdc.gov/parasites/naegleria/treatment.html](http://www.cdc.gov/parasites/naegleria/treatment.html).
The only known way to prevent *Naegleria fowleri* infections is to refrain from water-related activities. However, some common sense measures that might reduce risk by limiting the chance of contaminated water going up the nose include:

- Avoid water-related activities in bodies of warm freshwater, hot springs, and thermally-polluted water such as water around power plants.
- Avoid water-related activities in warm freshwater during periods of high water temperature and low water levels.
- Hold the nose shut or use nose clips when taking part in water-related activities in bodies of warm freshwater such as lakes, rivers, or hot springs.
- Avoid digging in or stirring up the sediment while taking part in water-related activities in shallow, warm freshwater areas.

Recreational water users should assume that there is always a low level of risk associated with entering all warm fresh water in southern tier states. Because the location and number of ameba in the water can vary a lot over time, posting signs is unlikely to be an effective way to prevent infections. In addition, posting signs on only some fresh water bodies might create a misconception that bodies of water that are not posted are Naegleria-free.

Information about the risks associated with *Naegleria fowleri* infection should be included in public health messages discussing general issues of recreational water safety and risk.

When preparing solutions of tap water for sinus irrigation the user should use tap water previously boiled for 1 minute (at elevations above 6,500 feet, boil for 3 minutes) and left to cool, or use filtered water using a filter with an absolute pore size of 1 micron or smaller, or use clearly marked distilled or sterile water in the irrigation device. Rinse the irrigation device after each use with water that has been previously boiled, filtered, distilled, or sterilized and leave the device open to air dry completely.
