Influenza & influenza-like illness (ILI) activity summary:

In week 42, influenza activity remained at low levels across the state. Influenza activity is expected to increase in the coming weeks as we head further into the season. Influenza seasons vary in timing, severity, and length. It is not possible to predict what the 2018-19 influenza season will be like in Florida.

ILI activity in children <18 years increased and was above normal levels. For more information, see page 9.

One new outbreak of influenza A unspecified was reported in a child daycare. Five influenza or ILI outbreaks have been reported so far this season. For a complete list of outbreaks reported so far this season, see page 14.

The majority of counties reported no or mild activity in week 42.

No influenza-associated pediatric deaths were reported in week 42. One influenza-associated pediatric death has been reported in Florida so far during the 2018-19 influenza season. For more information, see page 10.

Influenza vaccines are safe and are the best way to protect yourself and your loved ones from influenza and its potentially severe complications. Those who have not yet been vaccinated for the 2018-19 season should do so before the end of October. Flu vaccination prevents millions of flu illnesses and health care visits, and tens of thousands of hospitalizations each season nationally. While some people who get vaccinated do get sick, vaccination has been shown to make illness less severe.

Since July, the most common influenza subtype detected at the Bureau of Public Health Laboratories has been influenza A 2009 (H1N1), however, it is still too early to say if influenza A 2009 (H1N1) viruses will predominate throughout the season.

Influenza vaccines protect against the three or four strains research suggests will be most common. Influenza A 2009 (H1N1), influenza A (H3), and influenza B viruses are expected to co-circulate throughout the season. Influenza vaccines are designed to protect against all of these viruses.

In addition to getting vaccinated, the Florida Department of Health recommends you take every day precautions to prevent the spread of influenza and other respiratory viruses. Sick people should stay home until fever-free for at least 24 hours (without the use of fever-reducing medication). Wash your hands often with soap and water (if soap is not available, use an alcohol-based sanitizer) and avoid touching your eyes, nose and mouth.

Florida ILI Surveillance System Summary ................. 16

Influenza, or flu, is a respiratory infection caused by a variety of influenza viruses. Most experts believe influenza viruses spread primarily by droplets made when infected people cough, sneeze, or talk. Less often, a person might become infected with influenza by touching a surface or object contaminated with influenza virus and then touching their own mouth, eyes, or nose.

The best way to prevent influenza infection is to get vaccinated each year. Influenza vaccines protect against the three or four influenza viruses research suggests will be most common.

Influenza Surveillance:

Individual cases of influenza are not reportable in Florida with the exception of novel influenza A (a new subtype of influenza A) and influenza-associated pediatric deaths. All outbreaks, including those due to influenza or influenza-like illness (ILI), are reportable in Florida.

Influenza surveillance is conducted to detect changes in the influenza virus. These data are used to help determine the annual northern hemisphere vaccine composition and to prepare for potential pandemics.

Surveillance is also conducted to identify any unusually severe presentations of influenza, detect outbreaks, and determine the onset, peak, and wane of the influenza season to assist with influenza prevention, particularly in high-risk populations like the very young, adults aged ≥65 years, and pregnant women.

The influenza reporting year is defined by standard reporting weeks outlined by the Centers for Disease Control and Prevention, where every year 52 or 53 reporting weeks. Increased surveillance for influenza in Florida for the 2018-19 season began in week 40 (ending October 6, 2018) and will extend through week 20 (ending May 21, 2019). This report is produced by the Department on a weekly basis during the regular influenza season and an abbreviated report is published on a biweekly basis during the summer months.

Surveillance case definitions for ILI vary slightly across surveillance systems. For more information on Florida’s influenza surveillance systems and associated case definitions, see page 16.

Statewide Activity

Figure 1: In week 42, the percent of emergency department and urgent care center visits for ILI statewide increased and was slightly above levels observed at this time in previous seasons.

Figure 1 (above) shows the percent of visits for influenza-like illness (ILI) for facilities participating in ESSENCE-FL (n=335) statewide for the current season (week 40-42, 2018) and the last three seasons (2017-18, 2016-17, and 2015-16). The ESSENCE-FL ILI syndrome captures visits with chief complaints that include the words “influenza” or “flu,” or chief complaints that include the words “fever” and “cough,” or “fever” and “sore throat.” For more information on the use of ESSENCE-FL for influenza and ILI surveillance, see page 16.
Statewide Activity

Figure 2: In week 42, Florida reported sporadic geographic spread of influenza to the Centers for Disease Control and Prevention.

Defining geographic spread of influenza:

No activity: no laboratory-confirmed cases of influenza and no reported increase in the number of cases of influenza-like illness (ILI)

Sporadic: small numbers of laboratory-confirmed influenza or a single laboratory-confirmed influenza outbreak has been reported, but there is no increase in cases of ILI.

Local: outbreaks of influenza or increases in ILI and recent laboratory confirmed influenza in at least two but less than half the regions of the state.

Regional: outbreaks of influenza or increases in ILI and recent laboratory-confirmed influenza in at least two but less than half the regions of the state with recent laboratory evidence of influenza in those regions.

Widespread: Outbreaks of influenza or increases in ILI cases and recent laboratory-confirmed influenza in at least half the regions of the state with recent laboratory evidence of influenza in the state.

Figure 2 (above) shows Florida's self-reported geographic spread of influenza as reported to the Centers for Disease Control and Prevention, week 40, 2014 to week 42, 2018.

Figure 3: In week 42, the percent of patients with ILI reported by ILINet outpatient providers statewide decreased slightly and remained similar to levels observed at this time in previous seasons.

For ILINet, ILI is defined as a fever ≥100°F AND sore throat and/or cough in the absence of another known cause.

Figure 3 (to the right) shows the percent of patients with influenza-like illness (ILI) reported by ILINet outpatient providers statewide (n=49), week 40, 2015 to week 42, 2018.

Figure 4: In week 41 (ending 10/13/18), the number of pneumonia and influenza deaths identified statewide decreased and was below levels observed at this time in previous seasons.

Figure 4 (to the left) shows pneumonia and influenza (P&I) deaths* for all Florida counties from the Bureau of Vital Statistics, as reported into ESSENCE-FL, week 40, 2015 to week 41, 2018.

*Current season P&I counts are preliminary numbers that may change as more data are received. The most recent data available are displayed here.
County Influenza Activity

Figures 5-6 (above) show county influenza activity data as reported by county health departments in EpiGateway. These data are collected on a weekly basis and are used to determine influenza activity levels for each county (Figure 5). County health departments also report their weekly influenza activity trend (Figure 6).

Figure 7: In week 42, the majority of counties reported no or minimal influenza activity across all settings.

Figure 7 (above) shows the results of the influenza activity assessment completed by county health departments for week 42, 2018. As part of the assessment, county health departments are asked to evaluate influenza activity in certain settings within their county. The assessment scale for activity ranges from no or minimal activity to very high activity.
Outbreaks of Influenza and Influenza-like Illness

Statewide Outbreaks

Outbreak summary:

In week 42, one outbreak of influenza A unspecified was reported.

Additional outbreak reports are expected in the coming weeks as the influenza season progresses.

As of week 42, a total of five outbreaks of influenza or influenza-like illness have been reported for the 2018-19 season. A complete list of the outbreaks reported so far this season is available on page 14.

Settings:

The outbreak in week 42 was reported in a Lake County child daycare.

All of the outbreaks reported so far this season have been in facilities serving children (schools/camps and child daycares).

Laboratory testing:

No specimens have been available for testing at the Bureau of Public Health Laboratories thus far for this outbreak.

Hospitalizations and deaths:

No hospitalizations or deaths have been reported thus far for this outbreak. So far this season, one hospitalization was reported in one outbreak. No deaths have been reported in any of these outbreaks.

For detailed information on notable outbreaks reported in week 42, see page 15.

For information on outbreaks in facilities serving children, see page 9.

For information on outbreaks in facilities serving adults aged ≥65 years, see page 11.

Figure 9: In week 42, one new outbreak was reported in a child daycare. All of the outbreaks reported so far this season have been in facilities serving children (schools/camps and child daycares).
Laboratory Surveillance

Figure 10: So far this season, the majority of influenza-positive specimens at the Bureau of Public Health Laboratories have been influenza A 2009 (H1N1).

Figure 10 (above) shows the number of influenza-positive specimens at the Bureau of Public Health Laboratories (BPHL) by lab-event date,* week 30, 2018 (beginning July 22, 2018) through week 42, 2018.

While the majority of specimens submitted to BPHL in week 42 have tested positive for influenza B thus far, influenza A 2009 (H1N1) is the most commonly detected influenza subtype at BPHL so far this season. The number of influenza-positive specimens submitted to BPHL has remained low overall, which is expected for this time in the season. **It is still too early to say what the predominantly circulating strain of influenza will be during the 2018-19 season.**

*“Lab event date” is defined as the earliest of the following dates associated with influenza testing at the laboratory: date specimen collected, date received by the laboratory, date reported, or date inserted.

Background:

The Bureau of Public Health Laboratories (BPHL) routinely submits influenza isolates to Centers for Disease Control and Prevention (CDC) for antigenic characterization. The purpose of this testing is to monitor for changes in circulating influenza viruses and compare how similar currently circulating influenza viruses are to the reference viruses used for developing influenza vaccines. While antigenic characterization can provide an indication of the influenza vaccine’s ability to produce an immune response against circulating influenza viruses, annual vaccine effectiveness estimates remain necessary to determine how much protection has been provided to the population by vaccination.

BPHL submits two influenza A (H3) isolates, two influenza A 2009 (H1N1) isolates, and four influenza B virus isolates (two Victoria lineage and two Yamagata lineage) every two weeks to CDC (as available). CDC’s most recent FluView (www.cdc.gov/flu/weekly/index.htm) offers national context for data displayed in Table 2 and Figure 8 (below).

The official recommendation is quadrivalent vaccines administered for the 2018-19 northern hemisphere influenza season contain the following: (1) an A/Michigan/45/2018 (H1N1)pdm09-like virus, (2) an A/Singapore/INFIMH-16-0019/2016 (H3N2)-like virus, (3) a B/Colorado/06/2017-like virus (B/Victoria/2/87 lineage), and (4) a B/Phuket/3073/2013-like virus (B/Yamagata/16/88 lineage). It is recommended that the influenza B component of trivalent vaccines administered for the 2018-19 northern hemisphere influenza season be a B/Colorado/06/2017-like virus. For more information, visit: www.who.int/influenza/vaccines/virus/recommendations/2018_19_north/en/.

Figure 11: As of week 42, all of the influenza specimens submitted to CDC for antigenic characterization were antigenically similar to their respective vaccine reference strain.

Figure 11 (to the left) shows the percentage of specimens submitted to CDC that are antigenically similar to reference strains representing the recommended vaccine components of the 2018-19 northern hemisphere vaccine, week 30, 2018 (beginning July 22, 2018) to week 42, 2018 by virus type.

As of week 42, 2018, antigenic characterizations results are still pending for two influenza A (H3N2) isolates and three influenza A 2009 (H1N1) isolates submitted to CDC by BPHL during this timeframe.
Regional Activity

Figures 12-18 (below) show the percent of emergency department and urgent care center visits for influenza-like illness (ILI) at ESSENCE-FL participating facilities (n=335) from week 40, 2015 to week 42, 2018. Data are organized by Regional Domestic Security Task Force Regions (see Figure 19).

**Figure 12:** In region 1, ILI activity decreased during week 42 but remained within levels observed at this time in past seasons.

**Figure 13:** In region 2, ILI activity decreased during week 42 and remained within levels observed at this time in past seasons.

**Figure 14:** In region 3, ILI activity increased during week 42 but remained within levels observed at this time in past seasons.

**Figure 15:** In region 4, ILI activity remained stable during week 42 and was within levels observed at this time in past seasons.

**Figure 16:** In region 5, ILI activity increased during week 42 and was slightly above levels observed at this time in past seasons.

**Figure 17:** In region 6, ILI activity increased during week 42 and was above levels observed at this time in past seasons.

**Figure 18:** In region 7, ILI activity increased during week 42 and was above levels observed at this time in past seasons.

**Figure 19** (to the right) shows emergency departments and urgent care centers reporting data to ESSENCE-FL (n=335) with Regional Domestic Security Task Force Regions outlined in bold.
At-Risk Populations: Children

Background:
Children, especially those with underlying health conditions (like asthma or diabetes), are at higher risk for severe complications from influenza infection. The single best way to protect children from influenza is to get them vaccinated every year. The Florida Department of Health (the Department) encourages you and your family to get vaccinated by the end of October. To find a flu shot near you, please visit: www.floridahealth.gov/findaflushot.

Figure 20: In week 42, the percent of emergency department and urgent care center visits for ILI in children <18 years increased and was above levels seen at this time in past seasons.

Outbreaks in Facilities Serving Children

Outbreak summary:
In week 42, one outbreak of influenza or ILI was reported in facilities serving children (schools/camps or child daycares): one outbreak of influenza A unspecified in a Lake County child daycare.

All of the outbreaks reported so far this season have been in facilities serving children. It’s not uncommon for outbreaks in facilities serving children to be reported early in the season, ahead of facilities serving other groups.

Additional outbreaks in these settings are expected in the coming weeks as we head further into the influenza season.

Annual influenza vaccination as the first and most important step in protecting against influenza infection. Flu vaccines are safe and the best way to prevent influenza or influenza-associated complications. The Department recommends you get yourself and your family vaccinated by the end of October.

The Department also recommends you take everyday actions to prevent the spread of influenza (and other viruses) such as keeping sick children home until they are fever-free for 24 hours (without the use of fever reducing medication), covering your nose and mouth with your arm when you cough or sneeze, washing your hands often with soap and water, and avoiding touching your eyes, nose, and mouth.

Settings:
One outbreak was reported in a child daycare and one outbreak was reported in a child daycare.

Laboratory testing:
Thus far, no specimens have been available for testing at the Bureau of Public Health Laboratories for this outbreak.

Hospitalizations and deaths:
No hospitalizations or deaths have been reported so far for this outbreak. So far this season, one hospitalization in one outbreak in a child daycare was reported. No deaths have been reported in any of these outbreaks.
At-Risk Populations: Children

Figures 21-22: In week 42, no new influenza-associated pediatric deaths were reported.

In week 42, no new influenza-associated pediatric deaths were reported. One influenza-associated pediatric death has been reported so far this season in an unvaccinated child with no known underlying medical conditions.

The Florida Department of Health receives reports of influenza-associated pediatric deaths each season. Most deaths are reported in unvaccinated children and children with underlying medical conditions.

Children, especially those with certain health conditions are at increased risk of severe complications from influenza. Influenza vaccination has been shown to reduce a child’s likelihood of dying from influenza by up to 60%. For more information, please visit: www.cdc.gov/media/releases/2017/p0403-flu-vaccine.html.

At-Risk Populations: Pregnant Women

Background:

Influenza is five times more likely to cause severe illness in pregnant women (even those who are generally healthy) compared to women who are not pregnant. Pregnant women with certain underlying medical conditions (such as asthma or heart disease) are at even greater risk for severe complications from influenza. Inactivated influenza vaccines are safe, provide the best protection for pregnant women and their babies, and are recommended at any time during pregnancy. Vaccination during pregnancy provides maternal antibody protection to infants too young to be vaccinated for influenza and has been shown to protect pregnant women from influenza-associated hospitalization and preterm birth. For more information, talk to your health care provider.

Figure 21 (above) shows the number of influenza-associated pediatric deaths as reported in Merlin by vaccination status, week 40, 2014 to week 41, 2018.

Figure 22 (above) shows the number of influenza-associated pediatric deaths as reported in Merlin by medical history, week 40, 2014 to week 42, 2018.

Figure 23 (to the left) shows the number of visits* to emergency department and urgent care centers with chief complaints of influenza infection and pregnancy, as reported in ESSENCE-FL, week 40, 2015 to week 42, 2018.

*This count underrepresents the true number of pregnant women presenting for care to emergency departments and urgent care centers with influenza, however, the overall trend has been validated through review of discharge data collected by the Agency of Health Care Administration.
At-Risk Populations: Adults ≥65 Years Old

Background:
Adults ≥65 years old are at higher risk for severe complications from influenza infection, including hospitalization and death. While influenza seasons vary in intensity, adults in this age group bear the greatest burden of severe influenza disease. In Florida, an average of 80% of seasonal pneumonia and influenza deaths occurred in adults aged ≥65 years over the last five influenza seasons. Annual vaccination is the best way to prevent influenza infection.

Figure 24: In week 42, the percent of emergency department and urgent care center visits for ILI in adults ≥65 years increased, but remained similar to levels observed at this time in past seasons.

Outbreaks in Facilities Serving Adults ≥65 Years

Outbreak summary:
In week 42, no new outbreaks of influenza or influenza-like illness (ILI) were reported in facilities serving adults ≥65 years (assisted living facilities, nursing facilities, or other long-term care facilities).

No outbreaks in these settings have been reported so far this season. Outbreaks are expected as we head further into the influenza season.

The Florida Department of Health (the Department) recommends annual influenza vaccination as the first and most important step in protecting against influenza infection and the Department strongly urges long-term care facility administrators and directors to actively recommend and offer influenza vaccines to all residents, staff, and health care personnel who have not yet received their 2018-19 vaccinations. Those who have no yet been vaccinated for the 2018-19 season should do so by the end of October.

Figure 24 (to the left) shows the percent of influenza-like illness (ILI) visits among adults ≥65 years at emergency departments and urgent care centers, as reported into ESSNECE-FL, week 40, 2015 to week 42, 2018.

Figure 25 (above) shows the number of outbreaks where antiviral treatment was administered to ill individuals by week in facilities serving adults ≥65 years, as reported in Merlin.

Figure 26 (above) shows the number of outbreaks where antiviral chemoprophylaxis was administered to at-risk individuals by week in facilities serving adults ≥65 years, as reported in Merlin.
Respiratory Syncytial Virus Surveillance

Background:

Respiratory syncytial virus (RSV) is a common respiratory virus that usually causes mild, cold-like symptoms. Young children and older adults, especially those with certain underlying health conditions, are at higher risk for severe illness from RSV. Prophylaxis is available for children who qualify. For more information, contact your health care provider.

RSV Surveillance:

A statewide RSV surveillance system was implemented in Florida to support clinical decision-making for prophylaxis of premature infants. The determination of unique seasonal and geographic trends of RSV activity in Florida has important implications for prescribing patterns for initiating prophylaxis to children at high risk for complications from RSV infection. The American Academy of Pediatrics currently recommends preapproval for prophylactic treatment be made based on state surveillance data. For more information on RSV surveillance systems used in Florida, see the last page of this report.

Florida’s RSV season is longer than the rest of the nation and has distinct regional patterns. The Florida Department of Health established regional RSV regions and seasons based on activity thresholds provided by the Centers for Disease Control and Prevention (see Figure 27). Currently, all five of Florida’s regions are in RSV season.

To learn more about RSV in Florida, please visit: www.floridahealth.gov/rsv.

Week 42 (October 14-20, 2018) Activity Summary:

In week 42, RSV activity in children <5 years increased statewide and was above levels observed at this time in previous years.

No new outbreaks of RSV were reported. One outbreak of RSV has been reported so far this season.

No new possible RSV-associated pediatric deaths were identified in week 42. A total of three possible RSV-associated pediatric deaths have been identified so far in 2018 and one of those deaths was investigated and ruled out. Investigations will occur to determine if the remaining two deaths meet case definition.

Figure 28: In week 42, the percent of emergency department and urgent care center visits for RSV among children <5 years increased and was above levels observed at this time in previous years.

*The overall trend displayed in Figure 28 has been validated through review of hospital discharge data collected by the Agency for Health Care Administration.
Figure 29: In week 42, the percent of specimens testing positive for RSV decreased and was below levels observed at this time in previous years.

Figure 29 (to the right) shows the percent of specimens testing positive for respiratory syncytial virus (RSV), as reported by hospital laboratories (n=6), week 30, 2015 to week 42, 2018.

Figure 30: In recent weeks, the percent of specimens testing positive for rhinovirus increased and remained higher than other respiratory viruses under surveillance.

Figure 30 (to the left) shows the percent of laboratory results testing positive for eight common respiratory viruses, as reported by laboratories participating in the National Respiratory and Enteric Virus Surveillance System (NRVESS) and laboratories reporting validated respiratory virus data to the Florida Department of Health via electronic laboratory reporting (n=6), week 30, 2018 (beginning July 22, 2018) to week 42, 2018.

Figure 31: In week recent weeks, RSV was the non-influenza respiratory virus most frequently identified in specimens submitted by ARIES providers.

Figure 31 (to the right) shows the number of specimens submitted by Acute Respiratory Infection Epidemiology and Surveillance Program (ARIES) providers (n=4) testing positive for 12 common respiratory viruses as reported by the Bureau of Public Health Laboratories, week 30, 2018 (beginning July 22, 2018) to week 41, 2018 (ending October 13, 2018).

Note: The most recent data available are displayed here. Laboratory results for submitted specimens that have not yet been tested in full will be included in future reports.

Summary of Notable Influenza and Influenza-like Illness (ILI) Outbreaks Reported in Week 42, 2018:

In week 42, 2018, no notable outbreaks of influenza or ILI were reported.
Florida ILI Surveillance System Summary

**ESSENCE-FL Syndromic Surveillance and Vital Statistics Portal** Data source for figures 1, 4, 12-20, 23, 24, and 28

Electronic Syndromic Surveillance System for the Early Notice of Community-based Epidemics (ESSENCE-FL) measures trends in influenza-like illness (ILI) visits from emergency departments (ED) and urgent care clinics (UCC) and influenza mortality by using death certificates from the Bureau of Vital Statistics. Participating EDs and UCCs (n=335) electronically transmit visit data into ESSENCE-FL daily or hourly.

For statewide and regional data on ILI, visits are counted as ED or UCC visits to participating facilities that include the words “influenza” or “flu” in patient chief complaints. Chief complaints with the terms “fever” and “cough,” or “fever” and “sore throat” are also counted as ILI.

For pneumonia and influenza (P&I) mortality surveillance, death record literals are queried using a free-text query that searches for references to P&I on death certificates. Any mention of P&I in the death certificate literals, with certain exceptions, is counted as a P&I death. Deaths counts are aggregated and presented by date of death.

For respiratory syncytial virus (RSV) surveillance, visits are counted as ED or UCC visits to participating facilities for which RSV or RSV-associated illness is included in the discharge diagnosis.

For RSV mortality surveillance, death record literals are queried using a free-text query that searches for references to RSV on death certificates. Any mention of RSV, syncytial, and bronchiolitis in the death certificate literals, with certain exceptions, is counted as a RSV death. These deaths are also investigated to ensure they meet case definition.

**Florida ILINet** Data source for figures 2 and 3

ILINet is a nationwide surveillance system composed of sentinel providers, predominately outpatient health care providers. Florida has 118 sentinel providers enrolled in ILINet who submit weekly ILI and total visit counts, as well as submit ILI specimens to the Bureau of Public Health Laboratories for virologic surveillance. For healthcare providers interested in enrolling in ILINet, contact your local county health department.

ILINet is also used as a portal in which the Florida Department of Health (the Department) reports Florida’s geographic spread of influenza each week to the Centers for Disease Control and Prevention (CDC).

**County Influenza Activity in EpiGateway** Data source for figure 5-7

County health department (CHD) epidemiologists report their county’s influenza and ILI surveillance data weekly into the Department’s EpiGateway website. Data from these reports is used to classify influenza activity as: no activity, mild, moderate, or elevated. Setting-specific influenza activity and influenza trend information is also reported by CHDs as available. EpiGateway data provided by CHDs creates a county-by-county breakdown of influenza and ILI activity around the state.

**Outbreak Reporting in Merlin** Data source for figures 8, 9, 25, and 26; tables 3 and 4

Merlin tracks influenza and ILI outbreak investigations by CHDs. Reports by CHDs include the type of respiratory disease causing the outbreak, settings where outbreaks are occurring, and recommendations made to mitigate the spread of disease. CHD epidemiologists report outbreaks of influenza or ILI into Merlin, Florida’s reportable disease surveillance system.

Outbreaks in assisted living facilities, nursing facilities, and long-term care facilities are defined as two or more cases of influenza or ILI. In schools/camps and child daycares, outbreaks are defined as three or more epidemiologically linked cases of influenza or ILI. The Department does not count household clusters as outbreaks.

**Bureau of Public Health Laboratories (BPHL)** Data source for figure 10 and table 1

BPHL performs testing and subtyping on surveillance specimens from sentinel providers, outbreak investigations, patients with severe or unusual influenza presentations, and medical examiners.

**United States World Health Organization Collaborating Laboratories Influenza Virus Surveillance** Data source for figure 11; table 2

The United States World Health Organization Collaborating Laboratories Influenza Virus Surveillance is a system that captures antigenic characterizations results for specimens submitted by BPHL to CDC for testing.

**Case-Based Influenza Surveillance** Data source for figures 21 and 22

Death in a child whose laboratory-confirmed influenza infection has been identified as a contributing to the child’s death are reportable in Florida. Influenza-associated pediatric deaths are documented by CHDs in Merlin.

In addition, an individual of any age infected with novel or pandemic influenza strain(s) is reportable in Florida. Pandemic strain influenza cases are documented by CHDs in Merlin.

For more information about reportable diseases, please visit [www.Floridahealth.gov/diseasereporting](http://www.Floridahealth.gov/diseasereporting).

**Laboratory Viral Respiratory Surveillance** Data source for figures 29 and 30

The National Respiratory and Enteric Virus Surveillance System (NREVSS) is a CDC surveillance system that captures on eight commonly circulating respiratory viruses as reported by participating laboratories in Florida. NREVSS data are combined with validated electronic laboratory data from Florida laboratories that submit RSV laboratory results via electronic laboratory reporting. Together, this information is used to monitor the temporal and geographic patterns of these viruses.

**Acute Respiratory Infection Epidemiology and Surveillance (ARIES) Program** Data source for figure 31

Acute Respiratory Infection Epidemiology and Surveillance Program (ARIES) is a nationwide surveillance system composed of 17 participating jurisdictions. Florida has four sentinel providers enrolled in ARIES who submit weekly ILI counts, as well as submit ILI specimens to BPHL for testing.
