State influenza and influenza-like illness (ILI) activity:\(^1\):

In weeks 37-38, influenza and ILI activity remained low overall and was within expected levels for this time of year. Modest increases are expected over the coming weeks as the start of the 2019-20 season approaches.

Annual vaccination is the best way to protect yourself and your loved ones from influenza and its potentially severe complications. Now is the perfect time to get vaccinated.

In weeks 37-38, nine new respiratory disease outbreaks were reported. Twenty-nine respiratory disease outbreaks have been reported since May 19, 2019 (when the traditional influenza season ended). Of those, 17 had laboratory evidence of influenza.

No new influenza-associated pediatric deaths were reported in weeks 37-38. Six influenza-associated pediatric deaths have been reported since the beginning of the 2018-19 season.

In weeks 37-38, nine (50\%) of the 18 specimens submitted to the Bureau of Public Health Laboratories for influenza testing were positive for influenza: four influenza A (H3) and five influenza B Victoria lineage, however, slightly more influenza A (H3) circulation was observed over the last four weeks compared to influenza B Victoria lineage.

Since March 2019, the percent of specimens testing positive for rhinovirus remained higher than other respiratory viruses under surveillance (including influenza). For more information, see page 3.

In weeks 37-38, the percent of emergency department and urgent care center visits for ILI statewide increased and remained similar to levels observed at this time in previous years.

\(^1\) Predominant strain in this context refers to the most common influenza subtype detected at the Bureau of Public Health Laboratories over the last four weeks. The strain reported here may be different to the strain reported as predominant overall during the traditional 2018-19 season (September 30, 2018 through May 18, 2019) in past reports.

\(^2\) No new influenza-associated pediatric deaths and human cases of novel influenza A infection (any age) are reportable. All outbreaks, including those due to influenza or other respiratory disease are reportable in Florida. The Florida Department of Health uses a variety of different surveillance systems to measure influenza and ILI activity. A summary of the systems used in this report can be found on our website: FloridaHealth.gov/FloridaFlu and on page 4.
Statewide Off-Season Outbreaks:

In weeks 37-38, nine new respiratory disease outbreaks were reported. Of the nine outbreaks reported, five had laboratory evidence of influenza. At least one hospitalization was reported in two of the nine outbreaks. No deaths were reported in any of the nine outbreaks.

Twenty-nine respiratory outbreaks have been reported since May 19, 2019. Of those, 17 had laboratory evidence of influenza.

Sporadic outbreak reports are expected during the summer months. The number of reported outbreaks is expected to increase slightly as the traditional influenza season approaches.

In weeks 37-38, nine respiratory disease outbreaks were reported: three in assisted living facilities, one in a long-term care facility, two in primary/secondary schools, and three in child daycares.

In weeks 35-38, primarily influenza A (H3) and influenza B Victoria lineage viruses co-circulated. Of note, the number of influenza-positive specimens at BPHL remained low overall.
Weeks 37-38 (September 8-21, 2019) RSV Activity Summary:

In weeks 37-38, RSV activity in children <5 years old increased. Levels were slightly above those seen at this time in past years.

No new possible RSV-associated pediatric deaths were identified in weeks 37-38. One possible RSV-associated pediatric death has been identified so far in 2019.

Two new outbreaks of RSV were reported in weeks 37-38 in child daycares.

Currently, Florida’s north, central, southwest, and southeast regions are in RSV season.

Florida’s RSV season is longer than the rest of the nation and has distinct regional patterns. The RSV seasons shown here are based on activity thresholds provided by the Centers for Disease Control and Prevention.

The determination of unique seasonal and geographic trends of RSV activity in Florida has important implications for prescribing patterns for initiating prophylaxis to children at high-risk for complications for RSV infection. The American Academy of Pediatrics recommends preapproval for prophylactic treatment be made based on state surveillance data.

In weeks 37-38, the percent of emergency department and urgent care center visits for RSV among children <5 years increased. RSV activity in children <5 years was slightly above levels observed at this time in previous years.

The percent of specimens testing positive for rhinovirus decreased notably but remained higher than other respiratory viruses under surveillance.

---

1 The overall trend displayed in this figure has been validated through review of hospital discharge data collected by the Agency for Health Care Administration.

Florida Influenza and ILI Surveillance System Summary

ESSENCE-FL Syndromic Surveillance and Vital Statistics Portal

Electronic Surveillance System for the Early Notification of Community-Based Epidemics (ESSENCE-FL) is used by the Florida Department of Health to monitor trends in influenza-like illness (ILI) visits at participating emergency departments (EDs) and urgent care centers (UCCs). Participating EDs and UCCs (n=356) electronically submit visit data into ESSENCE-FL daily or hourly.

ED and UCC visits are counted as ILI if the chief complaints include the words “influenza” or “flu” (with certain exceptions). Chief complaints with the words “fever” and “cough” or the words “fever” and “sore throat” are also counted as ILI.

For RSV mortality surveillance, a free-text query searches for references to RSV in the causes of death on death certificates. Any mention of “RSV,” “syncytial,” or “bronchiolitis” in the literal causes of death (with certain exceptions) is counted as a possible RSV-associated death. Possible RSV-associated deaths in children <18 years old are investigated to ensure they meet the case definition outlined by the Council of State and Territorial Epidemiologists.

Outbreak Reporting in Merlin

Outbreak investigations are tracked in Merlin (Florida’s reportable disease surveillance system) by investigating county health departments (CHDs). Outbreak reports include implicated viruses or bacteria, the outbreak setting, and recommendations made to mitigate the spread of disease.

- Outbreaks in assisted living facilities, nursing facilities, and long-term care facilities: two or more cases of influenza, ILI, or acute respiratory illness (ARI)
- Outbreaks in facilities serving children (primary/secondary schools and child daycares): three or more epidemiologically linked cases of influenza or ILI
- Household clusters are not counted as outbreaks.
- ILI: fever and cough or fever and sore throat in the absence of another known cause
- ARI: two or more respiratory symptoms in the absence of another known cause

Laboratory Surveillance

The Florida Department of Health, Bureau of Public Health Laboratories (BPHL) performs real-time reverse transcription polymerase chain reaction (RT-PCR) influenza testing (including subtyping for influenza A viruses and lineage determination for influenza B viruses) for specimens submitted from sentinel providers, outbreak investigations, health care providers treating patients with severe or unusual influenza presentations, and medical examiners. BPHL also performs RT-PCR subtyping for influenza A-positive specimens and RT-PCR lineage determination for influenza B-positive specimens.

The National Respiratory and Enteric Virus Surveillance System (NREVSS) is a Centers for Disease Control and Prevention (CDC) surveillance system that captures data on eight commonly circulating respiratory viruses as reported by participating laboratories in Florida. Data collected in NREVSS are combined with data from Florida laboratories that submit validated electronic RSV laboratory results to the Florida Department of Health via electronic laboratory reporting. Together, these data are used to monitor the temporal and geographic patterns of these viruses.

Case-Based Influenza Surveillance

Death in a child whose laboratory-confirmed influenza infection has been identified as contributing to the child’s death is a reportable condition in Florida. Influenza-associated pediatric deaths are investigated by CHDs and reported in Merlin. In turn, the Florida Department of Health reports these deaths to CDC.

In addition, an individual of any age with suspected or laboratory-confirmed novel or pandemic influenza A is reportable in Florida. Suspected or confirmed novel influenza A cases are investigated by CHDs in collaboration with state and national experts. CHDs report cases in Merlin and, in turn, the Florida Department of Health reports these cases to CDC.

Geographic Spread of Influenza

On a weekly basis, the Florida Department of Health evaluates influenza and ILI surveillance data to determine the geographic spread of influenza in Florida and report the weekly determination to CDC. Geographic spread is not an indication of influenza severity. Geographic spread can be reported as sporadic, local, regional, or widespread.

- Sporadic: small numbers of laboratory-confirmed influenza or a single laboratory-confirmed influenza outbreak has been reported but there is no increase in cases of ILI
- Local: outbreaks of influenza or increases in ILI and recent laboratory-confirmed influenza in at least two but less than half the regions of the state
- Regional: outbreaks of influenza or increases in ILI and recent laboratory-confirmed influenza in at least two but less than half the regions of the state with recent laboratory evidence of influenza in those regions
- Widespread: outbreaks of influenza or increases in ILI cases and recent laboratory-confirmed influenza in at least half the regions of the state with recent laboratory evidence of influenza in the state
