Unvaccinated children are at increased risk of vaccine-preventable diseases like pertussis and varicella. Communities with a higher proportion of religious exemptions (REs) to vaccination are at increased risk of vaccine-preventable disease transmission.

The proportion of children age 4 to 18 years with new REs is increasing each month. Statewide, the estimated prevalence of REs among children age 4 to 18 years old is 3.0% with individual counties ranging from 0.4% to 6.6%. In December 2017, the statewide prevalence was 2.6%, and the prevalence has gradually increased each month since.

To learn more about REs at the local level, please visit FloridaHealth.gov/REmap.

For all vaccine-preventable diseases, timely and complete vaccination is the best way to prevent infection. Although vaccinated individuals can still become infected with diseases like pertussis or varicella, in general, those who have received at least 1 dose of vaccine have less severe outcomes than those who have never been vaccinated for the disease.
Hepatitis A Surveillance
December 2018

2018 Key Points

- 559 cases
- 14% cases linked to other cases
- 30-39 year olds had highest incidence
- 22% co-infected with hepatitis B or C

The number of reported hepatitis A cases steadily increased each month since April 2018 and has remained at or above the previous 5-year-average all year. The number of cases reported in December increased from the previous month and was the highest reported in 2018.

From January 1, 2018 through December 31, 2018, 559 hepatitis A cases were reported in 31 counties.

The number of reported hepatitis A cases more than doubled from 2016 to 2017 after remaining relatively stable in previous years. Case counts in 2018 have exceeded those seen in previous years and are more than double the case counts in the last 5 years.

The best way to prevent hepatitis A infection is through vaccination. In 2018, 97% of people with hepatitis A had never received a documented dose of hepatitis A vaccine. In December, 95% of infected people had not received the vaccine. Hepatitis A vaccine is recommended for all children at age 1 year and for certain high-risk groups of adults including illegal drug users and men who have sex with men. To learn more about the hepatitis A vaccine, talk to your doctor or visit: www.CDC.gov/Vaccines/HCP/VIS/VIS-Statements/Hep-A.html.
In 2018, 79 (14%) of 559 total cases of hepatitis A were epidemiologically (epi) linked to other cases. In December, 12% of cases were linked to other cases. In December 72% of relationships were household contact and 28% sexual contact.

In 2018, the incidence rate was highest among adults aged 30-39 years old at 7.1 cases per 100,000 population. In December, the incidence rate was highest among adults aged 30-39 years old at 1.9 cases per 100,000 population. In 2018, cases were reported primarily among men (67%) and persons who identify as non-Hispanic white (74%).

In 2018, 6 (1%) cases were co-infected with chronic hepatitis B, 108 (19%) cases were co-infected with chronic hepatitis C, and 10 (2%) cases were co-infected with both chronic hepatitis B and C. In December, 21% of cases were co-infected with chronic hepatitis B or C. Co-infection with more than 1 type of viral hepatitis can lead to more severe liver disease and increase the risk of developing liver cancer.

Hepatitis A surveillance goals
- Identify and control outbreaks and monitor trends
- Identify and mitigate common sources
- Monitor effectiveness of immunization programs and vaccines

To learn more about hepatitis A, please visit FloridaHealth.gov/HepA. For more information on the data sources used in Florida for hepatitis A surveillance, see the last page of this report.
Over half (57%) of the 534 cases likely acquired in Florida reported at least one of the risk factors below, while 43% reported no or unknown risk factors. The most commonly identified risk factor was drug use, reported by 263 (49%) cases. Injection drug use was just as common a risk factor as non-injection drug use. Homelessness, reported by 13% of cases, was also a common risk factor.

Individuals with any of these risk factors should receive the hepatitis A vaccine, and providers are encouraged to actively offer the hepatitis A vaccine to individuals at risk. Vaccination is the best way to prevent hepatitis A infection.

Hepatitis A infections can be severe, leading to inpatient hospitalization and sometimes death. In 2018, 386 (72%) cases likely acquired in Florida have been hospitalized because of their hepatitis A infection, and there were 2 hepatitis A associated deaths identified.

The Florida Department of Health is actively working to vaccinate those most at risk for hepatitis A infection. In recent months, the number of first doses of hepatitis A vaccine administered by both private providers and county health departments to adults age 18 years and older, as recorded in Florida SHOTS, increased. Vaccination is the best way to prevent hepatitis A infection.
The number of pertussis cases reported in December decreased from the previous month and was below the previous 5-year average. In general, more pertussis cases are reported during the summer months.

From January 1, 2018 through December 31, 2018, 331 pertussis cases were reported in 35 counties. Since 2014, the number of pertussis cases reported annually decreased. Pertussis is cyclic in nature with peaks in disease every 3-5 years. Pertussis cases last peaked between 2013 and 2014. In 2018, case counts remained consistent with those seen during non-peak years.

In December, 2 (10%) of 21 total pertussis cases were associated with transmission within households and no cases were outbreak-associated. For most pertussis cases, exposure to other known cases is never identified, and they are not able to be linked to outbreaks.

No new pertussis outbreaks were reported in December.

Eight pertussis outbreaks have been reported in 2018. Outbreak settings include schools (4 outbreaks), daycares (2 outbreaks), workplace (1 outbreak), and extended family (1 outbreak).
For each pertussis case reported in December, there was an average of 4 contacts for whom antibiotics were recommended to prevent illness. For those diagnosed with pertussis, antibiotics can shorten the amount of time they are contagious to others. Antibiotics can also be used to prevent illness in those who have been exposed to someone with pertussis while they are contagious.

In December, the rate of pertussis was highest among infants <1 year old at 1.3 cases per 100,000 population, which is consistent with previous months. Infants experience the greatest burden of pertussis infections, not only in number of cases but also in severity. Infants <2 months old are too young to receive vaccinations against pertussis, which is why vaccination of parents, siblings, grandparents, and other age groups is so important to help prevent infection in infants.

Vaccination is the best way to prevent pertussis infections. In December, more than half of individuals reported with pertussis had not received the recommended number of pertussis vaccinations for their age or had unknown vaccination status. Vaccination against pertussis is important for everyone including infants, children, teenagers, and adults. Pregnant women should get vaccinated during the third trimester of each pregnancy to protect their babies. See the last page of this report for links to vaccination schedules recommended by the Centers for Disease Control and Prevention.
Pertussis surveillance goals

- Identify cases to limit transmission in settings with infants or others who may transmit pertussis to infants
- Identify and prevent outbreaks
- Identify contacts of cases and recommend appropriate prevention measures, including exclusion, antibiotic prophylaxis, and immunization
- Monitor the effectiveness of immunization programs and vaccines

To learn more about pertussis, please visit FloridaHealth.gov/Pertussis. For more information on the data sources used in Florida for pertussis surveillance, see the last page of this report.
December Key Points

- **4** cases
- **1** outbreak
- 100% cases never immunized

In 2018, **15 measles cases were reported in 4 counties**. Fewer than 10 cases were reported each year from 2010 to 2017.

In 2018, a total of 15 Florida residents and 4 visitors with measles have spent time in Florida while infectious.

In December, all 4 reported cases were associated with an outbreak in Sarasota County. Heightened response during measles investigations helps to connect cases.

There were two outbreaks reported in 2018, representing 11 of the 15 cases that were reported.

Vaccination is the best way to prevent measles infections.

In December, all 4 cases were unvaccinated for measles.

Due to generally high vaccination rates, measles in Florida is rare but occurs every year and is most often associated with international travel. So far, no international travel has been identified among the cases.

National and International activity

Even though measles has been eliminated in the United States since 2000, cases occur every year, mostly among unvaccinated individuals. As of December 1, 292 confirmed cases of measles have been reported by 26 states and the District of Columbia in 2018. The 2-dose measles vaccination schedule has been successful at decreasing cases.

Recently, increased measles activity has been reported all over the world. The Centers for Disease Control and Prevention (CDC) issued a Level 1 Travel Alert for several countries with measles outbreaks. Travelers to these countries should make sure they are vaccinated against measles with the MMR (measles, mumps, and rubella) vaccine. For more information, please visit [wwwnc.cdc.gov/travel/notices](http://wwwnc.cdc.gov/travel/notices).

Measles surveillance goals

- Prevent transmission and severe disease
- Initiate control measures
- Monitor effectiveness of immunization programs and vaccines

To learn more about measles, please visit [FloridaHealth.gov/Measles](http://FloridaHealth.gov/Measles). For more information on the data sources used in Florida for measles surveillance, see the last page of this report.
**Varicella Surveillance**

**December 2018**

### December Key Points

- **149 cases**
- **3 outbreaks**
- <1 year olds had highest incidence
- 70% cases not up-to-date or unknown vaccination status

The number of varicella cases reported in December increased from last month and was above the previous 5-year average. In general, more varicella cases are reported during the late winter and summer months.

From January 1, 2018 through December 31, 2018, **905 varicella cases** were reported in 52 counties. The annual number of reported varicella cases decreased from 2015 to 2017. Thus far in 2018, case counts are notably above the total number of cases in previous years.

In December, **16 (11%)** of **149 total cases** were associated with transmission within households and **18 (12%)** cases were outbreak-associated. For most varicella cases, exposure to other known cases is never identified, and they are not able to be linked to outbreaks.

Three varicella outbreaks were reported in December. Two were reported in schools in Pinellas County (8 cases to date) and Columbia County (5 cases to date). One was reported in a daycare in Hillsborough County (11 cases to date). Individuals were identified in November and December for all three outbreaks reported this month.

11 total varicella outbreaks were reported in 2018, of which 6 occurred in schools, 1 in a daycare, and 4 in correctional facilities. The majority of outbreaks in schools have occurred in populations with high religious exemption rates.
In December, the varicella rate was highest among infants <1 year old at 3.9 cases per 100,000 population, which is consistent with previous months. Infants <1 year old are too young to receive varicella vaccination, which is why vaccination of siblings, parents, grandparents, and other age groups is so important to help prevent infection in infants.

Vaccination is the best way to prevent varicella infections. In December, over half of individuals reported with varicella had not received the recommended number of varicella vaccinations for their age or had unknown vaccination status. Vaccination against varicella is important for infants, children, teenagers, and adults. See the last page of this report for links to the Center for Disease Control and Prevention (CDC) recommended vaccination schedules.

In 2018, 42% of children aged 15 months to 5 years with varicella were not up-to-date on their varicella vaccinations. Although individuals who have been vaccinated can still get varicella, complete and timely vaccination remains the best way to prevent varicella and severe complications.

National activity
Varicella incidence decreased significantly following the vaccine becoming available in 1995 and has continued to decrease since 2006 when recommendations changed from 1 to 2 doses of varicella vaccine. From 2006 to 2015, all age groups had a substantial decrease in incidence with the largest decline in children aged 5 to 14 years. Although varicella is not reported to the CDC by all states, based on available data, the number of varicella cases nationally has steadily decreased each year from 2012 to 2015.

Varicella surveillance goals
- Identify and control outbreaks and monitor trends and severe outcomes
- Monitor effectiveness of immunization programs and vaccines

To learn more about varicella, please visit FloridaHealth.gov/Varicella. For more information on the data sources used in Florida for varicella surveillance, see the last page of this report.
Case Data
• Current case data are preliminary and will change as new information is gathered. The most recent data available are displayed in this report.
• Pertussis, varicella, hepatitis A, and measles are reportable diseases in Florida. Case information is documented by county health department (CHD) epidemiologists in Merlin, Florida’s reportable disease surveillance system.
• Only Florida residents are included in case counts, but contact investigations are conducted for all exposed individuals.
  • Pertussis, varicella, hepatitis A, and measles case counts include both confirmed and probable cases.
• Map counts and rates are determined by the individual’s county of residence; these data do not take into account location of exposure.
• CHD epidemiologists also report outbreaks of pertussis, varicella, and hepatitis A into Merlin.
  • Household-associated cases are defined as ≥2 cases exposed within the same household.
  • Pertussis and mumps outbreaks are defined as ≥2 cases associated with a specific setting outside of a household.
  • Varicella outbreaks are defined as ≥5 cases associated with a specific setting outside of a household.
  • Measles outbreaks are defined as any person acquiring measles while in Florida.
• For more information about reportable diseases, please visit FloridaHealth.gov/DiseaseReporting.
• For more information about Florida’s guides to surveillance and investigation, including disease-specific surveillance case definitions, please visit FloridaHealth.gov/GSI.

Population Data
• Population data used to calculate incidence rates are from FLHealthCHARTS (Community Health Assessment Resource Tool Set).
• For more information about FLHealthCHARTS, please visit FLHealthCharts.com.

Vaccination Data
• Vaccination data for identified cases are from Merlin, as documented by CHD staff.
• Vaccination status is determined using the Advisory Committee on Immunization Practices Recommended Immunization Schedule for Children and Adolescents Aged 18 Years or Younger, 2018.
• For more information about immunization schedules, please visit www.CDC.gov/Vaccines/Schedules/index.html.
• Individuals are considered up-to-date on vaccinations if they have received the recommended number of doses of vaccine for a particular disease for their age at the time of their illness onset. Individuals are considered under-vaccinated if they have received at least one but not all doses of vaccine recommended for a particular disease for their age at the time of their illness onset.
