Pertussis surveillance goals:
• Pertussis surveillance is conducted to identify cases to limit transmission in settings with infants or others who may transmit pertussis to infants, and identify and prevent outbreaks.
• Surveillance is also conducted to identify contacts of cases and recommend appropriate prevention measures, including exclusion, antibiotic prophylaxis and immunization and to monitor the effectiveness of immunization programs and vaccines. For more information on the data sources used in Florida for pertussis surveillance, see page 10.

Pertussis Cases by Month Reported

Figure 2 shows the number of confirmed and probable cases of pertussis reported into Merlin, January 2018 through July 2018 and the previous five-year average.

In July, the number of reported pertussis cases was the same as that in June and remained below the five-year average. In general, the number of reported pertussis cases tends to be highest during the summer months.
Figure 3 shows the number of confirmed and probable cases that were associated with at least one other case and the total number of confirmed and probable cases as reported into Merlin, July 2018 and the previous three-month average.

In July, 14 (36%) cases were associated with transmission within households and two (5%) cases were outbreak-associated.

Outbreak Summary:
In July, one outbreak of pertussis was reported that included cases previously reported in June. The outbreak consisted of five cases, and transmission occurred within an extended family.

See page 10 for outbreak definitions.

Figure 4 shows the number of confirmed and probable cases of pertussis, as reported into Merlin, and the number of contacts who were recommended antibiotics to prevent illness, July 2018 and 2018 to date.

For each case reported in July, there was an average of four contacts for whom antibiotics were recommended to prevent illness.

Figure 5 shows the age-specific incidence rates of confirmed and probable cases of pertussis, as reported into Merlin, July 2018.

In July, the incidence rate was highest among infants less than one year old at 5.3 cases per 100,000 population, which is consistent with previous months. Infants experience the greatest burden of pertussis infections, not only in number of cases but also in severity. Infants less than two months old are too young to receive vaccinations against pertussis, which is why vaccination of grandparents, parents, siblings, and other age groups is so important to help prevent infection in infants.
Pertussis Surveillance

Vaccination History for Pertussis Cases

**Figure 6** shows the vaccination status of pertussis cases by age group for confirmed and probable cases of pertussis, as reported into Merlin, January through July 2018 (n=188).

Over half of individuals aged six months to five years were not up-to-date on their pertussis vaccinations. In general, those who have received at least one pertussis vaccination have less severe outcomes than those who have never been vaccinated. Over half of individuals 19 years and older had unknown vaccination status.

See page 10 for links to CDC-recommended vaccination schedules.

Pertussis Cases by Vaccination Status

**Figure 7** shows the percent of confirmed and probable pertussis cases for each vaccination status, as reported into Merlin, July 2018.

Although individuals who have been vaccinated can still get pertussis, complete and timely vaccination remains the best way to prevent pertussis and severe complications.

In July, 5% of cases were too young for vaccination. Vaccination against pertussis is important for infants, children, teenagers, and adults. Pregnant women should get vaccinated during the third trimester of each pregnancy to protect their babies.

Pertussis Outcomes

**Figure 8** shows the percent of confirmed and probable cases of pertussis with select outcomes by vaccination status, as reported into Merlin, July 2018 and the previous three-month average.

In July and the previous three months, cases who were too young for vaccination were more likely to require inpatient hospitalization. Cases who were never vaccinated or had unknown vaccination status were more likely to visit the emergency department in July.

In general, older individuals are more likely to experience paroxysmal cough while younger individuals are more likely to experience posttussive vomiting and whoop. Infants less than one year old primarily experience apnea.
Case Data
• Current case information is preliminary and will change as new data are gathered. The most recent data available are displayed in this report.
• Pertussis, varicella, and mumps are reportable diseases in Florida. Case information is documented by county health department (CHD) epidemiologists in Merlin, Florida’s reportable disease surveillance system.
• CHD epidemiologists also report outbreaks of pertussis, varicella, and mumps into Merlin.
  • Household-associated cases are defined as two or more cases exposed within the same household.
  • Pertussis and mumps outbreaks are defined as two or more cases associated with a specific setting outside of a household.
  • Varicella outbreaks are defined as five or more cases associated with a specific setting outside of a household.
• For more information about reportable diseases, please visit www.Floridahealth.gov/diseasereporting.
• For more information about Florida’s guides to surveillance and investigation, including disease-specific surveillance case definitions, please visit www.Floridahealth.gov/gsi.
• For the full article on a Minnesota outbreak of measles, please visit www.cdc.gov/mmwr/volumes/66/wr/mm6627a1.htm.

Population Data
• Population data used to calculate incidence rates are from FLHealthCHARTS (Community Health Assessment Resource Tool Set).
• For more information about FLHealthCHARTS, please visit www.flhealthcharts.com.

Vaccination Data
• Vaccination data for identified cases are from Merlin, as documented by CHD epidemiologists.
• Vaccination status is determined using the Advisory Committee on Immunization Practices Recommended Immunization Schedule for Children and Adolescents Aged 18 Years or Younger, 2018.
• For more information about immunization schedules, please visit www.cdc.gov/vaccines/schedules/index.html.
• Individuals are considered up-to-date on vaccinations if they have received the recommended number of doses of vaccine for a particular disease for their age at the time of their illness onset. Individuals are considered under-vaccinated if they have received at least one but not all doses of vaccine recommended for a particular disease for their age at the time of their illness onset.
