Varicella Surveillance

November 2017

State varicella activity:

- Sixty confirmed and probable varicella cases were reported among 21 counties in November.
  - Reported varicella cases are starting to increase after having remained lower throughout the summer and fall. This is consistent with seasonal trends in past years.
  - Since January 1, 2017, 594 cases of varicella were reported among 52 of Florida’s 67 counties.
  - A decreasing trend in the number of confirmed and probable cases of varicella reported annually in Florida was observed from 2008-2014. Since then, the number of cases reported annually has remained elevated. Thus far in 2017, the number of varicella cases is slightly lower than the number observed in 2016.
  - One outbreak of varicella was reported in November among five residents of a mental health hospital in Gadsden County.
  - In November, children age less than one years old had the highest incidence of varicella. This is consistent with what was observed for the majority of months thus far in 2017.
  - Vaccination is the best way to prevent varicella infections. In November, 28 (47%) cases were not up to date on their varicella vaccinations. In general, those who have received at least one varicella vaccination even if they later develop disease have less severe outcomes than those who have never been vaccinated.
  - In November, infants infected with varicella who were too young for vaccination and those with unknown vaccination status were most likely to visit the emergency department. Few varicella cases require inpatient hospitalization.
  - To learn more about varicella, please visit http://www.floridahealth.gov/varicella.

National varicella activity:

- Varicella incidence decreased significantly since a vaccine became available in 1995 and has continued to decrease since 2006 when recommendations changed from one to two doses of varicella vaccine.
  - From 2006 –2015 all age groups saw a significant decrease in incidence with the largest decline in children age 5-9 years and age 10-14 years.
  - Although not all states report varicella cases to the CDC, based on available data the number of varicella cases nationally has steadily decreased each year from 2012-2015.

Surveillance goals:

- Varicella surveillance is conducted to identify and control outbreaks and monitor trends and severe outcomes.
- Surveillance is also conducted to monitor effectiveness of immunization programs and vaccines. For more information on the data sources used in Florida for varicella surveillance, see page 24.

Varicella Cases by Month Reported

Figure 37 shows the number of confirmed and probable cases of varicella reported into Merlin, January 2017 through November 2017 and the previous five-year average.

In November, the number of reported varicella cases increased. Thus far in 2017, the number of reported varicella cases has been below average except for peaks in February, July, and November, which was around the same time as four outbreaks. In general, varicella cases peak in the spring and fall.
Varicella Surveillance

Varicella Outbreaks

**Figure 38** shows the number of confirmed and probable cases that were associated with at least one other case and the total number of confirmed and probable cases as reported into Merlin, November 2017 and the previous three-month average. Cases associated with at least one other case are shown by type of association.

In November, 22 (37%) cases were associated with other cases, including five cases that were part of an outbreak and 17 that were connected to other cases through living in the same household.

**Outbreak Summary:**

An outbreak of varicella among five residents of a mental health hospital in Gadsden County was reported in November. From January 1, 2017 through October 31, 2017, a total of four outbreaks of varicella were reported. Three outbreaks were in correctional facilities and one outbreak was in a daycare setting.

Varicella Age-Specific Incidence Rates

**Figure 39** shows the age-specific incidence rates of confirmed and probable cases of varicella, as reported into Merlin, January 2017 through November 2017.

In November, the incidence rate was highest among infants less than one year old. This is consistent with trends seen earlier in 2017. Infants less than one year old are too young to receive vaccinations against varicella, which is why vaccination of other age groups is so important to help prevent infection in infants.

Vaccination History for Varicella Cases

**Figure 40** shows the vaccination status of varicella cases by age group for confirmed and probable cases of varicella, as reported into Merlin, January 2017 through November 2017 (n=494).

Varicella vaccinations are recommended at 12-15 months of age and 4-6 years of age. Of the 133 cases reported in children aged 15 months-5 years, the majority (81%) were up to date on their varicella vaccinations, while about half (55%) of the cases in children aged 6 to 18 years were up to date.
Varicella Cases in Vaccinated Individuals

**Figure 41** shows the percent of confirmed and probable varicella cases who were up to date on their varicella vaccinations, as reported into Merlin, January 2017 through November 2017 and the previous five-year average. **Figure 42** shows the percent of these cases who were under vaccinated during the same period.

Although individuals who have been vaccinated can still get varicella, vaccination remains the best way to prevent varicella and severe complications.

Varicella Outcomes

**Figure 43** shows the percent of confirmed and probable cases of varicella with select outcomes by vaccination status, as reported into Merlin, November 2017 and the previous three-month average.

In general, cases who were UTD on their vaccinations were less likely to experience fever and vesicle lesions. Cases too young to be vaccinated or not yet vaccinated were more likely to experience papule lesions.

In November, infants too young for vaccination and those with unknown vaccination status were most likely to visit the emergency department. Few varicella cases require inpatient hospitalization; recent cases requiring hospitalization were either too young for vaccination or of unknown vaccination status.
Case Data
- Pertussis, varicella, and mumps are reportable diseases in Florida. Case information is documented by county health department (CHD) epidemiologists in Merlin, Florida’s reportable disease surveillance system.
- CHD epidemiologists also report outbreaks of pertussis, varicella, and mumps into Merlin. Outbreaks are defined as two or more cases associated with a specific setting outside of the home. Two or more cases among members of the same household are considered household-associated cases.
- Current case information is preliminary and may change as more data are received. The most recent data available are displayed in this report.
- For more information about reportable diseases, please visit www.Floridahealth.gov/diseasereporting.

Population Data
- Population data used to calculate incidence rates are from FLHealthCHARTS (Community Health Assessment Resource Tool Set).
- For more information about FLHealthCHARTS, please visit www.flhealthcharts.com.

Vaccination Data
- Vaccination data from cases are from Merlin, as identified by CHD epidemiologists.
- Vaccination status is determined using the Advisory Committee on Immunization Practices Recommended Immunization Schedule for Children and Adolescents Aged 18 Years or Younger, 2017.
- Cases are considered up-to-date if they have received the recommended number of doses of vaccine for a particular disease for their age at the time of their illness onset. Cases are considered under vaccinated if they have received at least one but not all doses of vaccine recommended for a particular disease for their age at the time of their illness onset.
- For more information about immunization schedules, please visit https://www.cdc.gov/vaccines/schedules/index.html.
