Florida Department of Health**

## **Introduction**

The public health community uses infant mortality and birth weight statistics extensively as maternal and child health indicators because they are relevant, readily available, and reliable due to a relatively high level of completeness.

The purpose of this analysis is to identify geographic areas in the state that exhibit statistically significant differences in low birth weight (LBW) and infant mortality (IM) rates than would be expected considering the unique demographics of each county or Healthy Start Coalition (HSC) area.

IM and LBW rates in Florida vary across geographic areas. This variation is due, in part, to the unique demographic characteristics of the population in different geographic areas. In this analysis, adjustments are made to make valid comparisons among areas with different population sizes based on selected demographic characteristics. Three demographic characteristics are accounted for to calculate the expected IM and LBW: maternal race, marital status, and maternal education. These variables are used because of their known associations with the risks of LBW and IM.

Other demographic characteristics, such as young maternal age and smoking status, were not used to adjust IM and LBW estimates to avoid eliminating differences that could possibly be attributed to public health interventions. For example, counties or HSC areas with lower than expected LBW percentages may have implemented successful smoking cessation programs. If adjustments had been made for smoking status, differences between actual and expected statistics would not be apparent. In another example, births to women under the age of 20 can be influenced by teen pregnancy prevention interventions, and by the same logic, adjustments are not made for maternal age.

IM and LBW rates can also fluctuate due to random variation or chance. In this analysis, statistical methods are used to separate random from non-random variation, so rates reported as significantly higher or lower are most likely a result of non-random influences. Likewise, rates that are higher or lower than expected, but not statically significant, are most likely the result of random variation.

## **Methods**

The data used in this analysis were extracted from the birth records for Florida residents who were born in calendar years 2016 and 2017. Infant mortality is defined as the death of a child less than one year of age (0 to 365 days). Infants born weighing less than 2,500 grams at delivery are considered LBW. This analysis uses three demographic variables to perform statistical adjustment on expected IM and LBW estimates: maternal race, marital status, and maternal education. Each demographic variable has two defined values as follows: maternal race as non-black or black; marital status as married or not married; and maternal education as high school or above, or less than high school graduation. All possible combinations of the three demographic variables form nine mutually exclusive categories. The ninth category includes birth records for which any of the three demographic variables had a missing value. The nine categories are as follows:

<u>Category</u>	<u>Maternal Race</u>	<u>Marital Status</u>	<u>Maternal Education</u>
1	Non-Black	Married	High School or More
2	Non-Black	Married	Less than High School
3	Non-Black	Not Married	High School or More
4	Non-Black	Not Married	Less than High School
5	Black	Married	High School or More
6	Black	Married	Less than High School
7	Black	Not Married	High School or More
8	Black	Not Married	Less than High School
9	Unknown	Unknown	Unknown

### **Calculating IM and LBW Expected Rates:**

Using the classification scheme shown above, nine state-level categories-specific IM expected rates were calculated from the 2016 vital records (the latest year available at the time of this analysis for complete linked birth and infant death data). The infant death linkage indicator is not recorded on the birth record until up to one year after a birth. Therefore, 2017 linked infant birth-death records were not completed at the time of this analysis and 2016 data were instead used to calculate expected IM estimates. This adjustment technique is referred to as indirect adjustment. To obtain the 2017 expected number of infant deaths by county or Healthy Start Coalition (HSC) area, each of the nine state-level categories-specific IM rates for 2016 were multiplied by the total number of county-level or HSC area births in 2017 and then summed. To compute the 2017 expected infant mortality rates for each county or HSC area, the 2017 expected number of infant deaths was used as the numerator and the total number of births in 2017 was used as the denominator. Using the nine state-level categories-specific rates to estimate county-specific or HSC area expected IM counts and rates accounts for the unique sociodemographic composition of mothers in each county or HSC area who gave birth to an infant and mothers whose infants had died by adjusting for the influence of maternal race, marital status, and maternal education.

These methods were applied in the same way to calculate expected LBW counts. However, 2017 state-level birth counts for each category were used to calculate expected county-level or HSC area LBW percentages because birth weight is recorded at the time of delivery.

The normal approximation to the binomial distribution formula was used to test for statistically significant differences between actual and expected rates in most of the counties or HSC areas. In instances where the number of infant deaths or number of low birth weight infants was less than 30, the Poisson formula was used. The correlation between the actual to expected ratios for IM and LBW across the counties or HSC areas was assessed.

In March 2004, the recording of maternal race on the birth record was changed to allow the selection of more than one race. For this analysis, births where the only maternal race recorded was black were classified as black and all others were classified as non-black.

### **Results**

The results of this analysis are shown in the following tables and maps for IM and LBW. In the tables, actual statistics are compared to expected statistics. The expected statistics are adjusted for the selected demographic characteristics in each county or HSC area, as described above. Counties or HSC areas with statistically significant higher than expected actual statistics are indicated in the tables with an H and those with an L indicate statistically significant lower than

expected actual statistics. The maps display the results of the statistical tests for significance. Counties or HSC areas where the actual statistics are significantly higher or lower are shaded in different colors, as indicated by the legend on the maps.

There was not a statistically significant correlation between the actual to expected LBW ratios and the actual to expected infant death ratios (Kendall's rank correlation coefficient = 0.16; p value of 0.057).

Also included in this report are summary tables for the years 2013 through 2017 that show the Hs and Ls for the counties and HSC areas for each of the past five years.

## Summary

For 2017 IM rates: Actual vs. Expected

- Broward (4.88 vs. 6.60), Dade (5.09 vs. 6.01), and Palm Beach (4.45 vs. 6.42) counties (Table 1), which also each comprise their own HSC areas (Table 2), had statistically significant lower than expected IM rates. The counties and HSC areas with lower IM rates than expected are in the southeastern region of the state (Maps 1 and 2). Broward, Dade, and Palm Beach counties and their respective HSC areas presented lower IM rates than expected for all the five years studied (Tables 5 and 6).
- Bradford (17.73 vs. 6.03) and Levy counties (19.46 vs. 5.69) had statistically significant higher than expected IM rates (Table 1). Bradford and Levy counties are located within the Healthy Start of North Central Florida Coalition area, which also had a higher than expected IM rate (8.69 vs. 6.14). Duval (8.04 vs. 6.68) and Nassau (10.74 vs. 4.99) counties had statistically significant higher than expected IM rates and are located within the Northeast Florida Healthy Start Coalition area which also had a higher than expected (7.34 vs. 6.27) IM rate. Hernando County (10.95 vs. 5.67) had a higher than expected IM rate and is located within the Central Healthy Start Coalition area which also had a higher than expected IM rate (8.30 vs. 5.64). Orange County and its respective Orange County Healthy Start Coalition area (7.17 vs. 6.04) had a higher than expected IM rate. Polk County (7.77 vs. 5.98) had a higher than expected IM rate and is located within the Healthy Start Coalition of Hardee/Highlands/Polk Counties area which also had a higher than expected IM rate (8.04 vs. 5.94) (Tables 1 and 2). As can be observed on Map 1, all counties with higher than expected IM rates are generally located in the northeast, north central, and central parts of the state. Only the Healthy Start of North Central Florida area presented higher IM rates than expected in each of the last five years (Tables 5 and 6).

For 2017 low birth weight percentages: Actual vs. Expected

- Dade (8.36% vs. 8.70%), DeSoto (5.44% vs. 8.55%), Monroe (6.29% vs. 8.32%), Palm Beach (8.52% vs. 9.13%), and Sarasota (6.78% vs. 8.13%) counties, which also comprise their own respective HSC areas, each had statistically significant lower percentages of LBW than expected (Tables 3 and 4). Saint Johns (6.56% vs. 7.53%) had a statistically significant lower percentage of LBW than expected, but its associated in the Northeast Florida Healthy Start Coalition area, which had results within the expected range. The Healthy Start Coalition of Southwest Florida area (7.88% vs. 8.33%) had a lower LBW percentage than expected, but its constituent counties did not (Tables 3 and 4). These counties and Healthy Start Coalition areas with lower percentages of LBW are in the southern regions of the state (Map 4). Palm Beach

County/coalition area presented lower than expected percentages of low birth weight for five consecutive years (Tables 7 and 8).

- Alachua (10.86% vs. 9.24%), Putnam (12.34% vs. 9.31%), Suwannee (11.29% vs. 8.57%), and Union (12.95% vs. 8.29%) counties had significantly higher percentages of LBW than expected (Table 3). All four counties are included in the Healthy Start of North Central Florida area (8.69% vs. 6.14%), which had higher than expected LBW percentages as well (Table 4). Escambia (10.73% vs. 9.43%) and Hillsborough Counties/coalition areas (9.26 vs. 8.80%) had significantly higher percentages of low birth weight infants than expected. Volusia County (9.45% vs. 8.60%) and the coalition area where it is located, Healthy Start Prenatal and Infant Coalition of Flagler and Volusia Counties area (9.20% vs. 8.56%), had significantly higher percentages of LBW than expected. Holmes (11.61% vs. 7.98%) County had a statistically higher percentage of LBW than expected, but its associated HSC area, Chipola Healthy Start Coalition area, did not. Nassau (9.67% vs. 7.65%) County had statistically higher percentages of LBW than expected, but its associated HSC area, Northeast Florida Healthy Start Coalition area, did not (Tables 3 and 4). These counties are in the north and central regions of the state (Map 3). Escambia is the only county/coalition area with four years of higher percentages of LBW infants than expected (Tables 7 and 8), as well as the Healthy Start of North Central Florida, Inc. (Table 8).

## **Discussion**

This analysis should be considered a preliminary step in the continuing endeavor to reduce IM and low birth weight in Florida. The results of this analysis can be used to focus further studies and public health efforts on areas of the state where the risks of poor infant health outcomes are significantly higher, and to further analyze factors that contribute to the lower risks seen in some areas.

One limitation of this analysis is the high variability of rates in smaller populations compared to those with larger populations. Consequently, larger differences in rates for small counties or HSC areas may not be statistically significant while the same or smaller differences may be statistically significant in larger counties or HSC areas. Actual rates that are statistically significantly higher than the expected rates are most likely not a result of random fluctuations, and may indicate a public health problem requiring further investigation and intervention. However, higher rates that are not statistically significant may warrant further investigation as well. Smaller counties or HSC areas with higher than expected rates for a period of several years may also be cause for concern.

Since adjustments were used to account for the differing demographic composition in each county or HSC area, further analysis could focus on other factors not included in this report, such as Medicaid birth rates and mother's age at birth. Unique factors in each county or HSC area contribute to IM and LBW. Local area analysis of factors associated with these outcomes should be undertaken to better understand the reasons for statistically significant lower or higher than expected rates with separate analyses performed for each area of concern. Finally, it should be noted that in this analysis, rates for each county or HSC area are compared to the statewide rates, after adjustment for maternal race, marital status, and maternal education. The issue of whether the statewide rates should be used as a baseline in these comparisons is not addressed in this analysis.
