Pertussis Surveillance

December Key Points

18 cases

No new outbreak

1-5 year olds had the highest6 month average incidence

The number of pertussis cases reported in December increased from the previous month and was above the previous 5-year average.

In December 2023, **18 pertussis cases** were reported in **10 counties**, outlined in black in the map below. From October 2023 through December 2023, the average county rates varied throughout the state.

In 2023, 86 pertussis cases were reported in 24 counties. There was a 85% increase in the number of pertussis cases reported between July 2023–December 2023 (n=50) compared to July 2022–December 2022 (n=27 cases).

*The white bars indicate the total number of cases as of December for each year

In December 2023, four pertussis cases were household-associated. No pertussis cases were outbreak-associated. In the past 6 months, there was an average of 1 household-associated case, an average of 0 outbreak-associated cases and an average of 9 total cases. From July 2022–December 2022, there was an average of 0 household-associated cases, an average of 0 outbreak-associated cases and an average of 0 outbreak-associated cases and an average of 0 outbreak-associated cases, an average of 0 outbreak-associated cases and an average of 5 total cases. For most pertussis cases, exposure to other known cases is not identified and are not able to be linked to outbreaks.

Household-associated Outbreak-associated Total cases

6 Mo Avg Jul 2023-Dec 2023 6 Mo Avg Jul 2022-Dec 2022 0 5

There was an average of 2 contacts per case between July 2022 and December 2022 were reported and between July 2023 and December 2023. Contacts are classified as people whom antibiotics were recommended to prevent illness. Antibiotics can shorten the amount of time cases are contagious and can also be used to prevent illness in those exposed. Understanding pertussis transmission is a key factor in decreasing pertussis infections. In Florida, transmission setting is not routinely identified for non-outbreak cases, resulting in **59**% of cases reporting unknown setting in the past six months.

Pertussis Surveillance

In 2023, over half of cases reported were not up-to-date on their pertussis vaccinations. **In general, those who have received at least one pertussis vaccination have less severe outcomes than those who have never been vaccinated.** If a person was born before January 1st, 1982, the current pertussis immunization recommendation would not have been implemented when they were receiving their childhood immunizations. Based on the case's age, **36 cases** would not have been vaccinated under the current childhood immunization recommendations.

National activity

The number of pertussis cases gradually increased since the 1980s, peaking in 2012 at levels not seen since the 1950s. Since 2012, the number of pertussis cases started gradually decreasing. Pertussis incidence has remained highest among infants <1 year old and lowest among adults ≥20 years old since the 1990s.

Pertussis surveillance goals

- · Identify cases to limit transmission in settings with infants or others who may transmit pertussis to infants
- Identify and prevent outbreaks
- · Identify transmission settings in non-outbreak cases to prevent the spread of sporadic cases
- Identify contacts of cases and recommend appropriate prevention measures, including exclusion, antibiotic prophylaxis, and immunization
- · Monitor the effectiveness of immunization programs and vaccines
